## 1. Introduction

### 1.1. Purpose

The purpose of this system is to provide a secure and user-friendly platform for managing user accounts. It enables users to register, log in, access protected areas like their profile or dashboard, and log out safely.

### 1.2. Scope

The system will let users:

- Register new accounts.
- Log in using their credentials.
- Access a personal dashboard.
- Log out securely.

What it won't do:

- No third-party login features
- Advanced features like password recovery, email verification, or multi-factor authentication (unless required later)

### 1.3. Definitions, Acronyms, and Abbreviations

- **UI (User Interface):** The front-end part of the system used by the user (React UI).
- **API (Application Programming Interface):** Backend endpoints used by the UI to communicate with the system (Spring Boot API).
- **Authentication:** Verifying a user's identity (login process).
- **Authorization:** Controlling access to protected pages based on login status.
- **Session/Token:** Data used to keep the user logged in after successful authentication.
- **Database (DB):** Storage for user records (e.g., Users table).
- **Password Hashing:** Securing passwords by storing an encrypted/hashed version instead of plain text.

## 2. Overall Description

### 2.1. System Perspective

This system is a basic authentication module that can be part of a larger web application. It connects a React UI to a Spring Boot backend API, which interacts with a database to store and retrieve user data. The system enforces access control so protected pages cannot be opened when a user is logged out.

### 2.2. User Classes and Characteristics

- **Guest User:** Not logged in. Can access registration and login pages only.
- **Authenticated User:** Logged in user. Can access protected pages like dashboard/profile and can log out.

### **2.3. Operating Environment**

- **Client:** Web browser (Chrome/Edge/Firefox) running the React UI
- **Server:** Spring Boot backend application running on a server/local machine
- **Database:** MySQL (or any relational DB) storing the Users table
- **Tools/Tech:** React, Spring Boot, REST API, MySQL, Postman (optional for testing)

### **2.4. Assumptions and Dependencies**

- Users have internet/local network access to reach the system.
- The database server is running and accessible by the Spring Boot API.
- The backend will handle password hashing and authentication logic.
- The UI depends on backend API responses to allow/deny access to protected pages.

## **3. System Features and Functional Requirements**

Describe each major feature of the system and its functional requirements.

### **3.1. Feature 1: User Registration**

Description: Allows a guest user to create an account by providing required details.

Functional Requirements:

- The system shall allow a guest user to submit registration details (e.g., username/email and password).
- The system shall validate required fields and prevent empty/invalid inputs.
- The system shall store the new user record in the database with a hashed password.

### **3.2. Feature 2: User Login and Access Control**

Description: Allows users to log in and access protected pages

Functional Requirements:

- The system shall allow users to submit login credentials.
- The system shall verify credentials against stored user data in the database.
- The system shall block access to protected pages if the user is not authenticated.

### **3.3. Feature 3: User Logout**

Description: Allows authenticated users to safely end their session.

Functional Requirements:

- The system shall provide a logout action for authenticated users.
- The system shall clear the user's session/token after logout.
- The system shall redirect the user back to the login page after logout.

## **4. Non-Functional Requirements**

- **Security:** Passwords must be stored as hashed values (not plain text). Protected pages must require authentication.
- **Usability:** The UI should be simple and easy to navigate (clear register/login/logout buttons).
- **Performance:** Login and registration should respond quickly under normal use.

- **Reliability:** The system should handle invalid input gracefully (show error messages without crashing).
- **Maintainability:** Code should be modular (separate controller, service, repository classes).

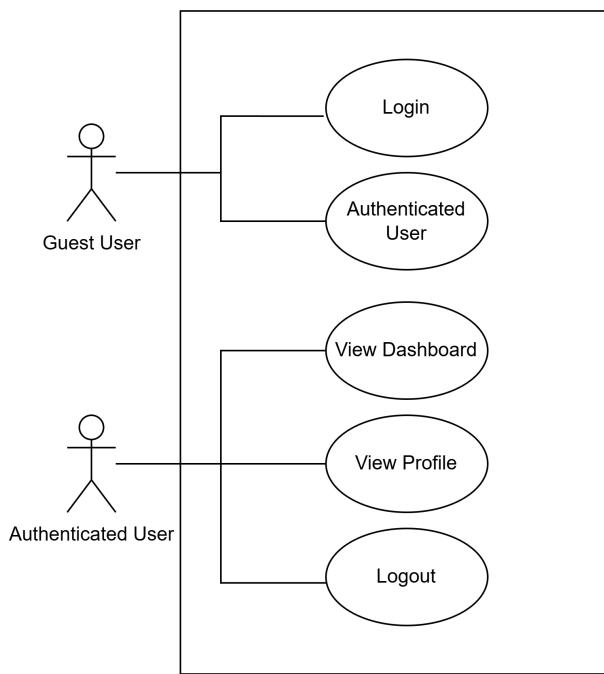

## 5. System Models (Diagrams)

*Insert the necessary diagrams for the system:*

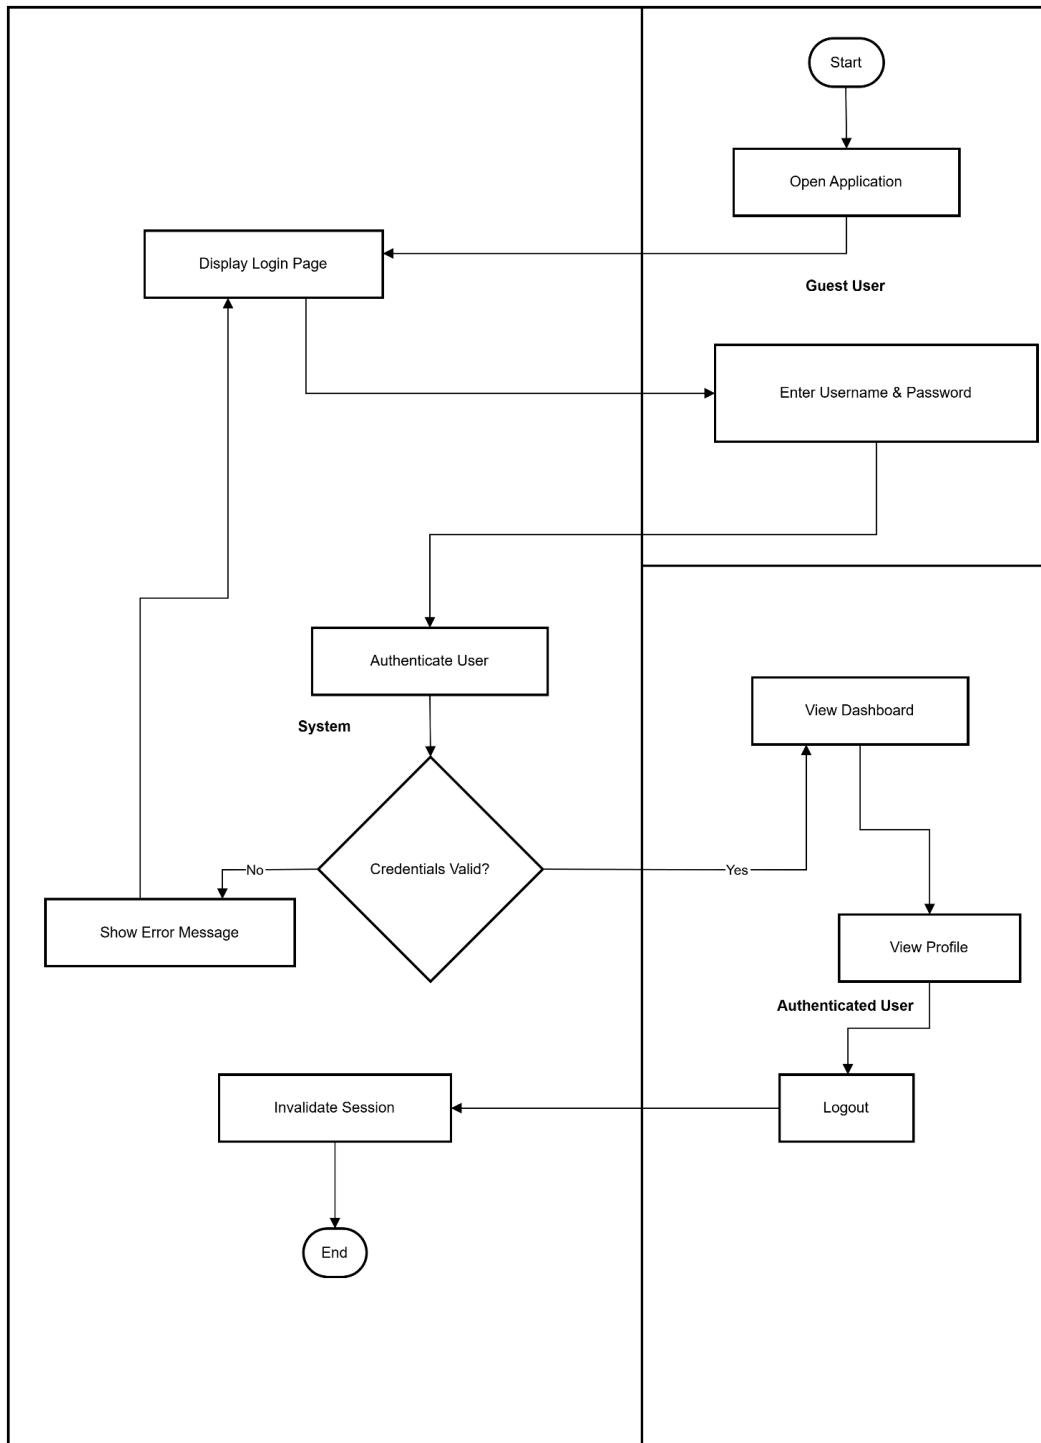

### 5.1. ERD

Users	
PK	<u>user_id</u>
	username first_name last_name email role password_hash

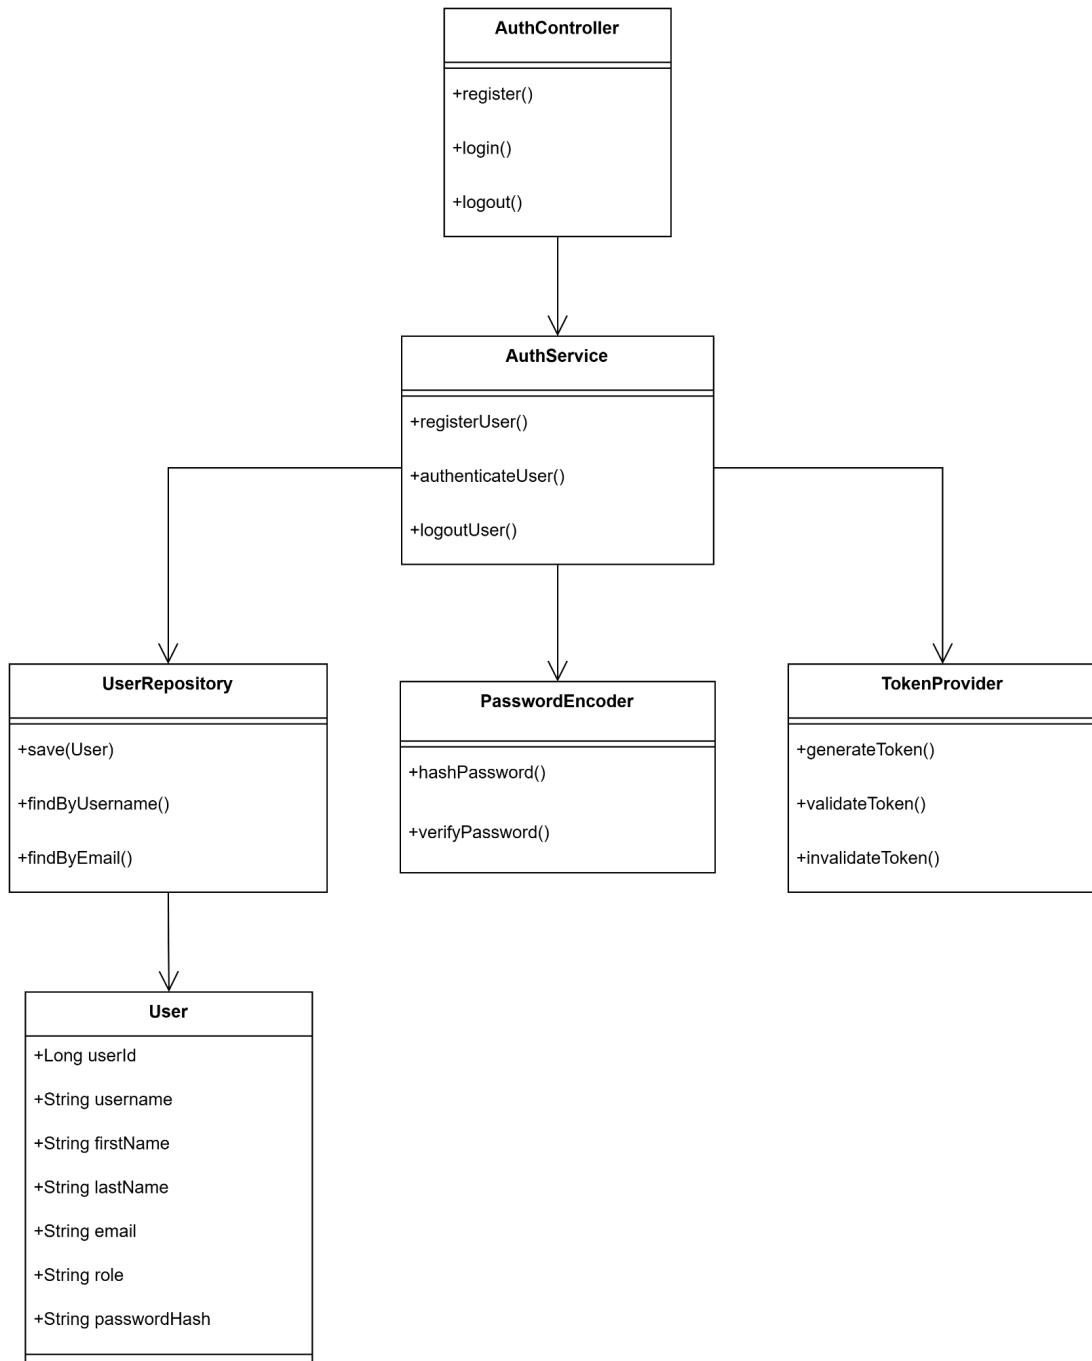

### 5.2. Use Case Diagram

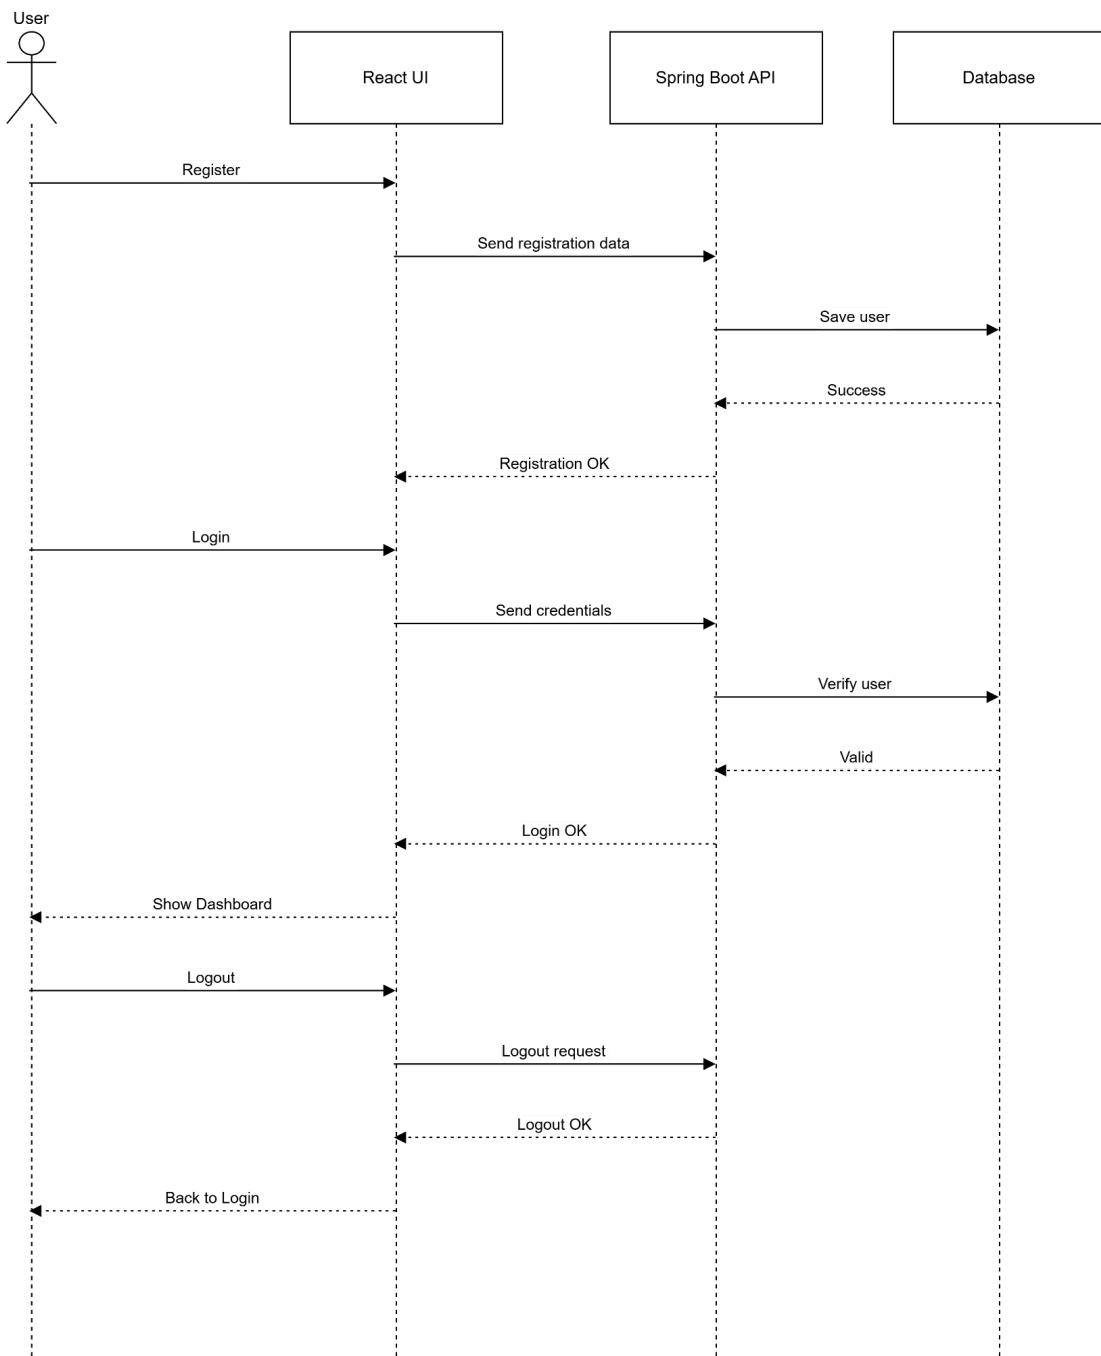

### 5.3. Activity Diagram

#### 5.4. Class Diagram

## 5.5. Sequence Diagram

## 6. Appendices

Include any additional information, references, or support materials.
